Abstract

Euglossa imperialis Cockerell, 1922 has recently been catalogued in the Cerrado of Mato Grosso do Sul, Brazil, and here we add both new and old data obtained from expeditions conducted in 10 municipalities of Mato Grosso since 2002. In this study we record this species for the first time in the wetlands of Cáceres and Barão de Melgaço, as well as on the northern Pantanal. Further studies are required to examine the variation in the coloration and other characteristics in *E. imperialis* populations from the northern and southern floodplains.

Keywords

Dispersal corridor, distributional gaps, dry forest, euglossines, gallery forest, orchid bees, wetlands.

Introduction

Belonging to the family Apidae and to the tribe Euglossini, the corbiculate bees of the genus *Euglossa* Cockerell, 1922 are represented by 140 described, valid species subdivided into seven subgenera: *E. (Euglossa)* Latreille, 1802, *E. (Glossura)* Cockerell, 1917, *E. (Euglossella)* Moure, 1967, *E. (Dasystilbe)* Dressler, 1978, *E. (Glossurella)* Dressler, 1982, *E. (Glossuropoda)* Moure, 1989 (see Ramirez et al. 2002), and *E. (Alloglossura)* Hinojosa-Díaz and Engel, 2012 (Hinojosa-Díaz and Engel 2012a).

The subgenus *Glossura* is represented by 16 species characterized by a) the scutellum biconcave, b) extremely elongated mouthparts apparatus, reaching

beyond the tip of abdomen, c) labrum greater in length than in width, and d) male midbasitarsus with internal keel. The internal keel is an important feature of *E. piliventris* Guérin-Méneville, 1845 and *E. imperialis* Cockerell, 1922 (Dressler 1978; Rebêlo and Moure 1995; Moure et al. 2012), the latter being the species addressed in the present study.

The publication of species' distributional data in specialized entomological journals and books contributes to our knowledge of species occurrences. It is irrefutable, however, that many data remain unpublished and, therefore, unavailable, which results in the persistence of numerous biogeographical gaps in the distribution. Such is the case of *E. imperialis*, a species of long-tongued euglossine bee of the subgenus *Glossura*.

Euglossa imperialis presents a large range of geographic distribution and has been reported from southern México (Chiapas, Quintana Roo, Veracruz) to Honduras (McCravy et al. 2016), Costa Rica, Nicaragua, Panama, Colombia, Ecuador, and Peru (Janzen et al. 1982; Ackerman 1983; Zimmerman and Madriñan 1988; Roubik 1993; Eltz et al. 1999; Otero and Sandino 2003; Roubik 2004; Roubik and Hanson 2004; Moure et al. 2012; Hinojosa-Díaz and Engel 2012b; Padrón et al. 2018). It has also been catalogued from Brazil (Moure 1989; Becker et al. 1991; Rebêlo and Garófalo 1991; Rebêlo 1993; Rebêlo and Moure 1995; Rebêlo and Silva 1999; Nemésio and Faria Junior 2004; Darrault et al. 2005; Anjos-Silva 2006a, 2006b, 2011; Faria Junior and Melo 2007; Oliveira et al. 2010; Schorn de Souza 2014; Figueiredo et al. 2015; Mateus et al. 2015; Oliveira-Junior et al. 2015; Antonini et al. 2017; Tosta et al. 2017; Cândido et al. 2018; Henrique et al. 2018; Coswosk et al. 2018; Machado et al. 2018).

In Brazil, this species has been catalogued from the Amazon rainforest (Moure 1989; Becker et al. 1991; Rebêlo and Silva 1999; Anjos-Silva 2011; Antonini et al. 2017; Cândido et al. 2018), the Cerrado (Rebêlo and Garófalo 1991, 1997; Rebêlo 1993; Rebêlo and Moure 1995; Nemésio and Faria Junior 2004; Anjos-Silva 2006a, 2006b, 2011; Oliveira et al. 2010; Schorn de Souza 2014; Figueiredo et al. 2015; Oliveira-Junior et al. 2015; Tosta et al. 2017; Henrique et al. 2018), besides the marine alluvial fan in Maranhão (Rebêlo and Silva 1999), the Pernambuco center of endemism (Darrault et al. 2005) and the Atlantic forest (Faria Junior and Melo 2007; Mateus et al. 2015; Coswosk et al. 2018; Machado et al. 2018).

Despite all the information available to date on the geographic distribution of *E. imperialis*, this species is unreported in the literature from southern Amazon to central Brazilian Cerrado. Especially when one considers the vast extent of the Amazon forest and the central Brazilian Cerrado domains and their diverse habitat conditions, it is evident that more studies are required. Here we bring data obtained by our research group in surveys conducted over the last 16 years in 10 regions within the Amazon, Cerrado, and Pantanal of Mato Grosso. All the specimens are deposited at the UNEMAT Bee Collection (EJASC) and are available to the public and specialists, as required.

Due to this lack of distributional data of this species in these areas, both authors checked all the specimens housed from 2002 to 2019 in the UNEMAT Bee Collection to start work on the current paper, and here we present the results of the surveys conducted in the Amazon–Paraguay divide.

Methods

Male orchid bees were caught in the legal reserve area of the Instituto Federal de Educação, Ciência e Tecnologia (IFMT) at the São Vicente campus (15.8226°S, 055.4184°W; 750 m altitude), in the Santo Antônio do

Leverger municipality, Mato Grosso (Figs 1, 2). The region characterized by a Tropical Savanna climate, Aw type on the Köppen-Geiger climate classification system (Peel et al. 2007).

The collections were performed monthly for three consecutive days, from November 2016 to June 2018, between 8 a.m. and 4 p.m., totaling 60 days of surveys, or 480 hours of direct observation of the bees in field surveys throughout the 20-month period. The expeditions had been granted permission to collect insects under ICMBio SisBio license numbers 12.778 and 18.147-2 in the name of EJAS.

Four pure chemicals were used throughout the surveys: β -ionone, 1,8-cineole, methyl salicylate, and vanillin. The males were caught with the use of entomological nets, sacrificed in ethyl acetate, and identified by a team member (Evandson José dos Anjos Silva). The specimens are housed in the Mato Grosso State University (UNEMAT) Bee Collection (EJASC, E J Anjos-Silva collection) of the Laboratory of Neotropical Bees and Wasps (LABEVE), at the Cáceres campus, Mato Grosso, Brazil. The systematic and morphological terminology follows that of Michener (2007) and Engel (1999, 2001).

In this study the geographic distribution of *E. imperialis* is discussed following the inclusion of the material deposited in the UNEMAT Bee Collection and obtained from a series of expeditions made from 2002 to 2018 (Fig. 3), together with unpublished monographs, dissertations and theses written by our team.

As a partial result of the survey made over the course of 20 months of collections of euglossines in the São Vicente Range, in the Santo Antônio do Leverger municipality, a total of 295 *E. imperialis* males were catalogued, of which 171 males (57.97%) were attracted to methyl salicylate, and 124 males (42.03%) to 1,8-cineole.

Considering all the *E. imperialis* males deposited in the UNEMAT Bee Collection, a total of 777 males were obtained from 10 municipalities of Mato Grosso, all of them catalogued in the Amazon–Paraguay drainage divide (Figs 1–4).

The majority of the males were attracted to methyl salicylate (455♂; 58.48%) and to 1,8-cineole (307♂; 39.51%). Other chemicals, like vanillin (3♂), eugenol (6♂), methyl cinnamate (3♂), benzyl acetate (1♂), and benzyl benzoate (2♂) attracted only 15 males (1.93%) of the species in the 10 study areas surveyed (Table 1).

The data presented here are relative to the 777 male specimens of *E. imperialis* collected by our team in 10 municipalities: Apiacás ($N = 2♂$), Novo Mundo ($N = 43♂$), Cotriguaçu ($N = 100♂$), Ribeirão Cascalheira ($N = 1♂$), Reserva do Cabaçal ($N = 208♂$), Pontes e Lacerda ($N = 3♂$), Chapada dos Guimarães (Chapada dos Guimarães National Park) ($N = 57♂$), Porto Estrela (Serra das Araras Ecological Station) ($N = 61♂$), Santo Antônio do Leverger (São Vicente Range) ($N = 295♂$), and Cáceres ($N = 7♂$). All occurrence data of *E. imperialis* in the Amazon rainforest, Amazon to Cerrado transition zones, Cerrado, and Pantanal of Mato Grosso are shown in Table 1; these occurrence points are all within the Amazon–Paraguay drainage divide (Figs 1–4).

Identification

Theodore D.A. Cockerell described *E. imperialis* based on four females from Rio Trinidad, Panama as rich green

Table 1. Study areas surveyed in 10 municipalities of Mato Grosso state in central-western Brazil. Occurrence points of *Euglossa imperialis* Cockerell, 1922 in the Amazon–Paraguay drainage divide, with chemicals used as baits and the list of specimens collected during the last 16 years (2002–2018), all of them housed in the UNEMAT Bee Collection (EJASC). Effort refers to active working day collections using entomological net from 8 a.m. to 4 p.m. or refers to the 2 L bottle trap used in orchid bee baiting programs in the basins since 2002.

and largely uniform in their coloration, yet appearing brilliant purple when seen in direct light. The broad hind margin of the first segment of the intense purple abdomen is the other feature in his original descriptions for the species (type: USNM 24882, March 16–23, 1912) (Cockerell 1922: 6). Extremely elongated mouthparts, which extend far beyond the apex of abdomen, were another feature he later added for the species (Cockerell 1917: 144).

The 777 males were identified based on the original descriptions and the illustrated keys by Rebêlo and Moure (1995). Comparisons were also made with specimens housed in the EJASC (LABEVE). The last revision made by Faria Junior and Melo (2007) was used to check the status of the species and the geographic distribution records.

The rich green coloration of the bees collected in the Amazon–Paraguay basins do not differ from that originally described for the females (Fig. 4), but there are no brilliant purple highlights on the abdomen as indicated by Cockerell (1922).

One should note the evident colour variation in the teguments when comparing the populations from Mato Grosso and Mato Grosso do Sul, varying from the dark green metallic coloration on the face and body of the males from the Amazon–Paraguay divide (Fig. 4) (e.g., Anjos-Silva 2006b; Anjos-Silva 2011; Figueiredo et al. 2015; this study), to the intense metallic blue with some green highlights observed in the populations of the Mato Grosso do Sul Cerrado (Henrique et al. 2018: 1062, figs 1, 4).

Discussion

After the publication by Henrique et al. (2018) in which they record 34 males of *E. imperialis* in two Cerrado fragments in Nova Alvorada do Sul municipality, Mato

Grosso do Sul, Brazil, we decided to review the literature and publish the data produced by our laboratory in recent years, with the aim of eliminating the biogeographical gaps for the species in the Amazon–Paraguay drainage divide.

With vast geographical distribution throughout the Neotropics, *E. imperialis* has been recorded from southern Mexico, and possibly Jamaica (Roubik 2004), to the Amazon forest and Cerrado domains in mid-west Brazil, the fragmented areas of the Cerrado, and the Atlantic forest in southern Brazil (Rebêlo and Moure 1995; Oliveira and Campos 1996; Rebêlo and Garófalo 1997; Silva and Rebêlo 1999; Roubik 2004; Anjos-Silva 2006a, 2006b, 2011; Moure et al. 2012; Figueiredo et al. 2015; McCravy et al. 2016; Antonini et al. 2017; Tosta et al. 2017; Cândido et al. 2018; Coswosk et al. 2018; Henrique et al. 2018; Machado et al. 2018; Padrón et al. 2018).

Males from Central America, the Amazon basin, and Atlantic forest regions were examined by Faria Junior and Melo (2007), but no differences in the morphological features were found between populations.

Rebêlo and Moure (1995) suggested that the absence of this species in Central Brazil is an artefact due to the lack of collections. According to Rebêlo (2001), the penetration of *E. imperialis* into southern South America might be related to introgression into the tropical forest along the Atlantic coast, or an old continuity through the northern portion of the Brazilian Planalto Central.

Although Brito et al. (2017) suggested that this species is highly associated with forest habitats, it is known to occur in areas within the Cerrado domain (Rebêlo and Moure 1995; Rebêlo and Garófalo 1997; Nemésio and Faria Junior 2004; Henrique et al. 2018), and it is frequently reported in gallery forests (Anjos-Silva 2006a; Silveira et al. 2015), which may act as biodiversity corridors (Moura and Schlindwein 2009).

The study area for our surveys is in the municipality

of Santo Antônio do Leverger, in the São Vicente Range, and inserted in a gallery forest located precisely between the Paraguay and the Araguaia basins and approximately 27 km from the flood plains of the Cuiabá river, where the Cerrado domains is the dominant landscape.

The abundance of *E. imperialis* males in the area surveyed from 2016 to 2018 in São Vicente Range ($N = 295\sigma$) was notably higher when compared to other site collections studied over the last 16 years (2002–2018) in Mato Grosso, varying from just a single male catalogued in the Xingu basin (Oliveira-Junior et al. 2015) to 208 males collected near the Monte Cristo waterfall in the Reserva do Cabaçal municipality, near Bolivia.

Both in the printed version (Moure et al. 2007) and in the online version (Moure et al. 2012), Moure et al. did not record *E. imperialis* from Mato Grosso. Only two records, one from Xingu basin (Oliveira-Junior et al. 2015) and the other from the Tapajós river (Figueiredo et al. 2015), were cited by Henrique et al. (2018).

The single male captured in the transition zones between the Amazon and Cerrado areas in Ribeirão Cascalheira (Oliveira-Junior et al. 2015) could lead to misinterpretation and to the conclusion that *E. imperialis* is a rare species in the Cerrado domain or even in the transition zones in the basins.

For the first time, we document *E. imperialis* from the Pantanal wetland areas, which are inundated by the Cuiabá river, a tributary of the Paraguay river, in the Pantanal of Cáceres, and in the Periquitos bay, in the urban area. The occurrence point of *E. imperialis* in the Cerrado of Nova Alvorada do Sul is roughly 100 km from Campo Grande, the capital of Mato Grosso do Sul, only 150 km from Paraná state, and approximately 700 km from Pantanal of Cáceres to the north.

In addition to including the previous records of this species in Mato Grosso, the Tapajós river basin (Figueiredo et al. 2015), and Xingu (Oliveira-Junior et al. 2015) cited by Henrique et al. (2018), our paper adds eight new records from the Amazon forest, Amazon to Cerrado transitions, Cerrado, and Pantanal of Mato Grosso. Our collections (this study) add a series of males collected in Apiacás, Cotriguaçu, Pontes e Lacerda, Reserva do Cabaçal, Cáceres, Porto Estrela, Santo Antônio do Leverger, Chapada dos Guimarães, all of them obtained in the Amazon–Paraguay drainage divide.

Ramirez et al. (2010) observed recurrent range splits connecting the Amazon and the Paraguayan Corridor, the Amazon and the Atlantic Forest, and the Amazon and the Andes. The Amazon region has the highest species diversity (68 species), and the Paraguayan Corridor the lowest (17 species). *Euglossa imperialis* has recently been sampled along latitudinal gradients of tropical, evergreen forests in central Bolivia at Vila Tunari (18°57'59"S, 065°24'44"W), Sacta (17°06'03"S, 064°47'02"W), and Buena Vista (17°30'49"S, 063°38'16"W) (Abrahamczyk et al. 2012). Curiously, this species has not been recorded in the dry forests of the mid-south of Mato Grosso state, Brazil (Água Milagrosa sinkhole and Jacobina Farm;

Anjos-Silva 2006) and in central Bolivia (Santa Cruz and Rio Seco; Abrahamczyk et al. 2012), which possibly indicates a preference for humid rather than dry habitats. However, with the addition of the new record for Bolivia (Abrahamczyk et al. 2012) and new and old records presented here, it is possible that the species uses gallery forests from the Amazon to the Cerrado to reach the Atlantic forest domains (see Ab'Sáber 1971), as previously document for *Eulaema cingulata* (Fabricius, 1804) (Anjos-Silva 2006a, 2006b, 2007) and *Euglossa cognata* Moure, 1970 (Anjos-Silva 2008). In this scenario, the male populations of *E. imperialis* possibly use the Pantanal wetland and the gallery forest as ecological corridors from the central Bolivian Amazon domain to reach the southeast and the Atlantic forest in Brazil (Rebêlo and Garófalo 1991, 1997; Rebêlo 2001; Ramirez et al. 2010; Mateus et al. 2015).

Acknowledgements

Support was provided by FAPEMAT (project numbers 334721/2008, 737955/2012, 222842/2015), INCT/CENBAM/PPBio/ UFMT/UNEMAT to MH Schorn de Sousa, and INCT PPBIO/MPEG/UNEMAT to EJAS. We thanks Marlúcia B. Martins (MPEG/MCT/CNPq/INPP) for support during the Apiacás project. We also thanks Jaquison C. Cunha, Sandro O. Pains, Felix A. Labaig, and Jessica DS Figueiredo for the help during collections, and Mariana T. Brito for the map design. Two reviewers provided useful comments on an early version on the manuscript.

Authors' Contributions

EJAS conceived, designed, and performed the study. EJAS and MHSS (Cotriguaçu and Santo Antônio do Leverger) performed the research and interpretation of the data and both authors wrote the paper.
